A photograph of a small stream flowing through a forest. The stream is narrow and shallow, with water visible in the center. The banks are covered with dry, yellowish-brown grass and some moss. The background is filled with bare trees and branches, suggesting a late autumn or winter setting. The text is overlaid on the upper half of the image.

Mapping headwater streams using LiDAR: Finding streams beyond the blue lines

Neil Olson

New Hampshire Geological
Survey/Department of Environmental
Services

Headwater streams underrepresented in the maps

- North Carolina: National Hydrography Dataset (NHD) underestimates by 64% Benstead and Leigh (2012)
- Massachusetts: NHD underestimates 21% of the field-verified streams Brooks and Colburn (2011)
- North Carolina: NHD underestimates by 56% Colson et al. (2008)

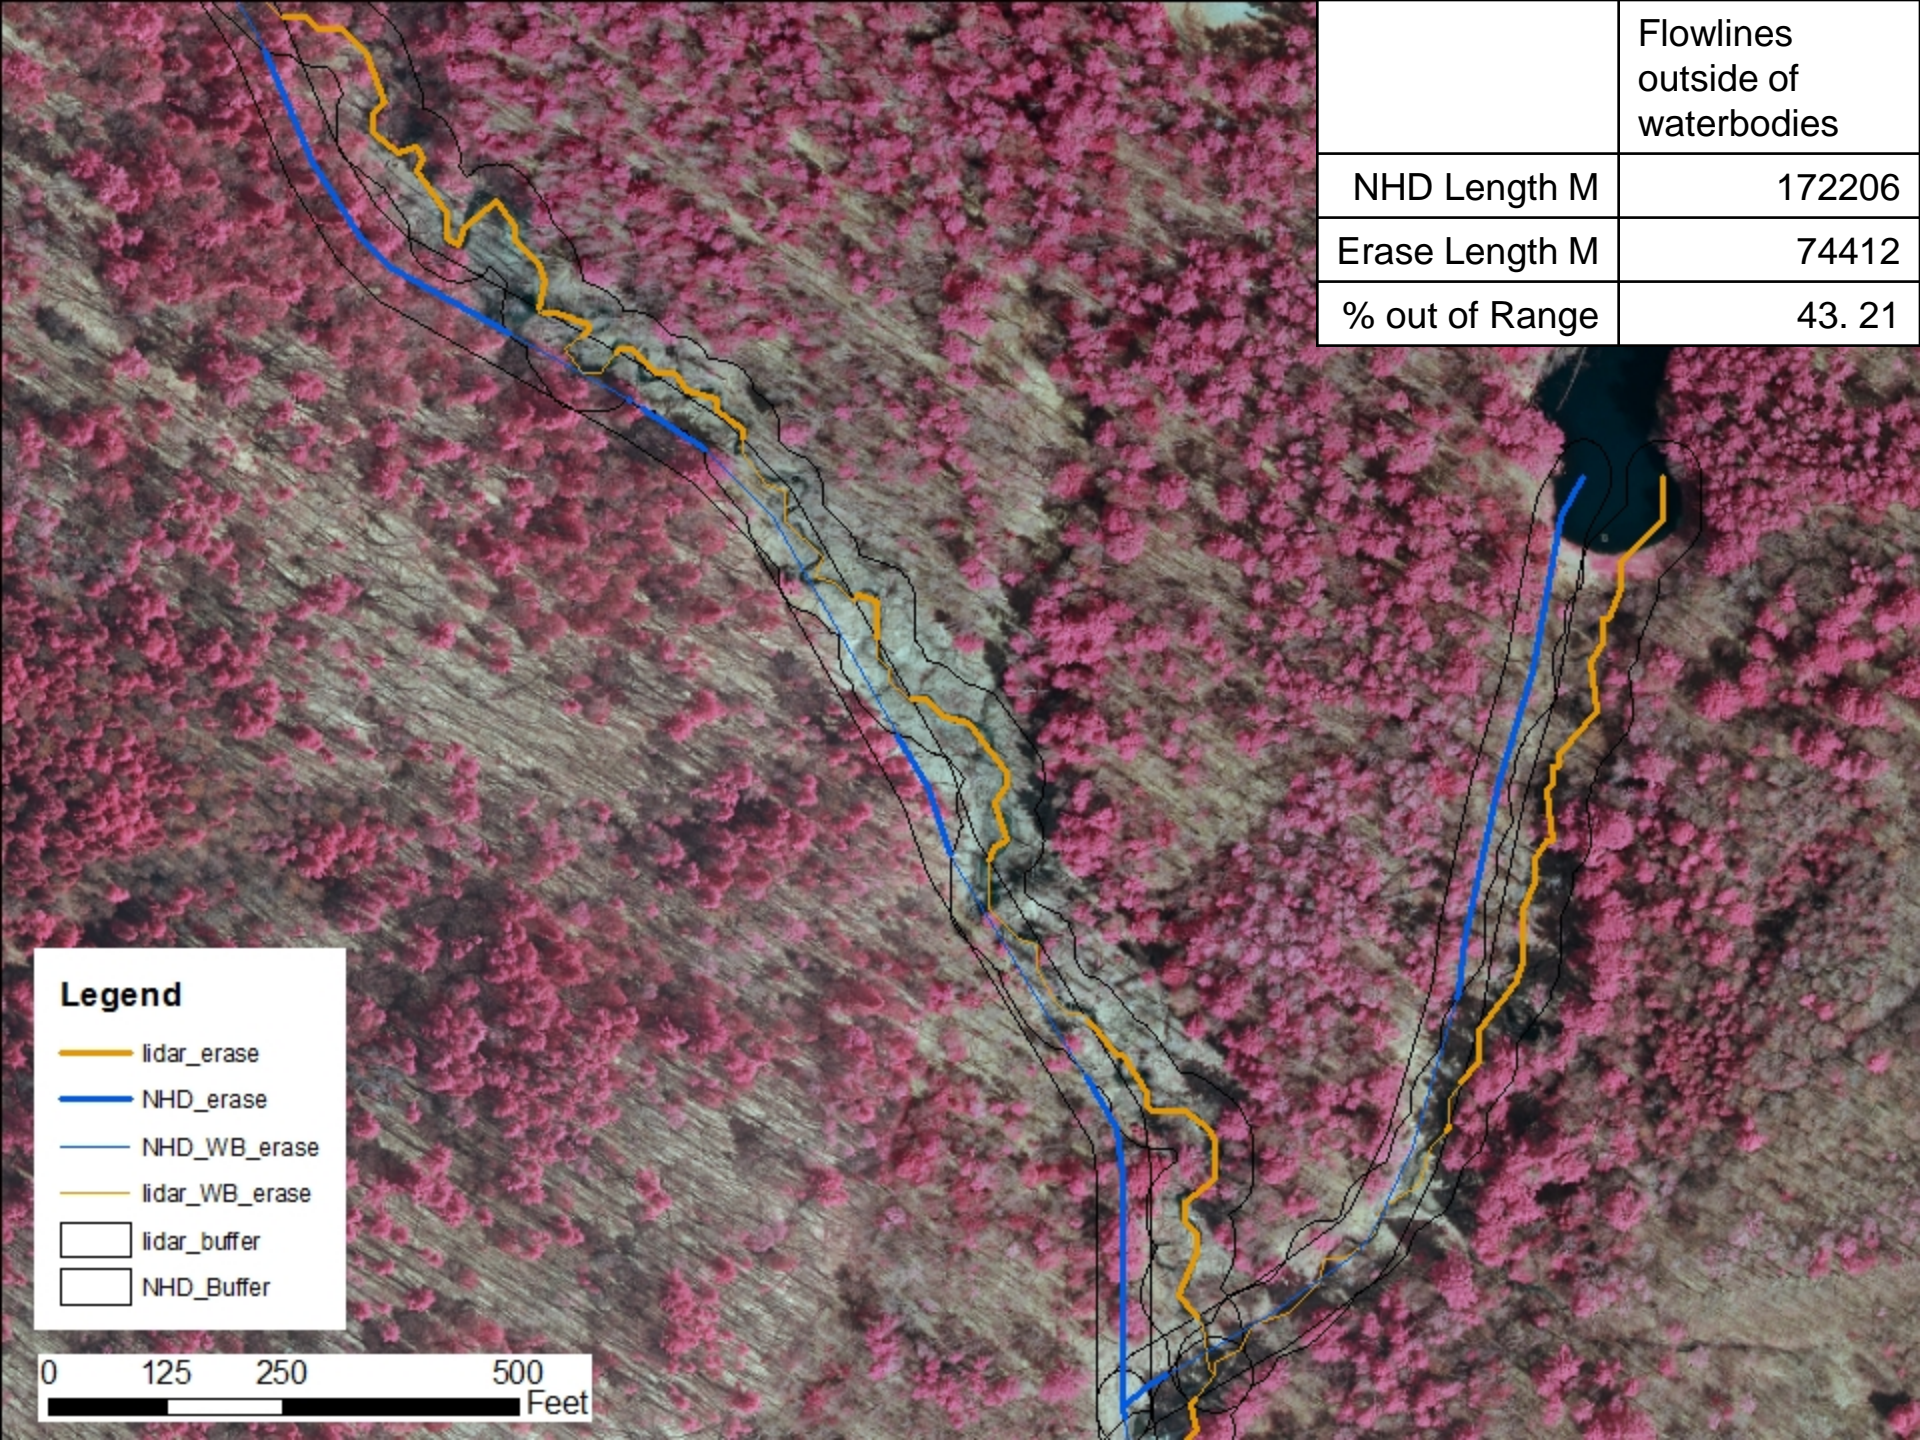

Difficulties with photo-interpretation

- New Hampshire is the most forested state in the contiguous US (88.9%) (Nowak and Greenfield 2012)
- You can't map what you can't see

National Map standard:
Horizontal accuracy of 40 ft for 90% of streams

0 125 250 500
Feet

	Flowlines outside of waterbodies
NHD Length M	172206
Erase Length M	74412
% out of Range	43. 21

BotHat (closing-DEM)

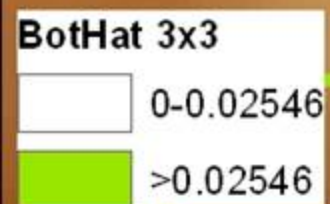

Methods

- Find channelized areas
- Find valley areas
- Find areas where water would accumulate
- Find areas where these coincide and represent a large area
- Use these as seed points
- Accumulate the seed points and convert to lines

Original DEM

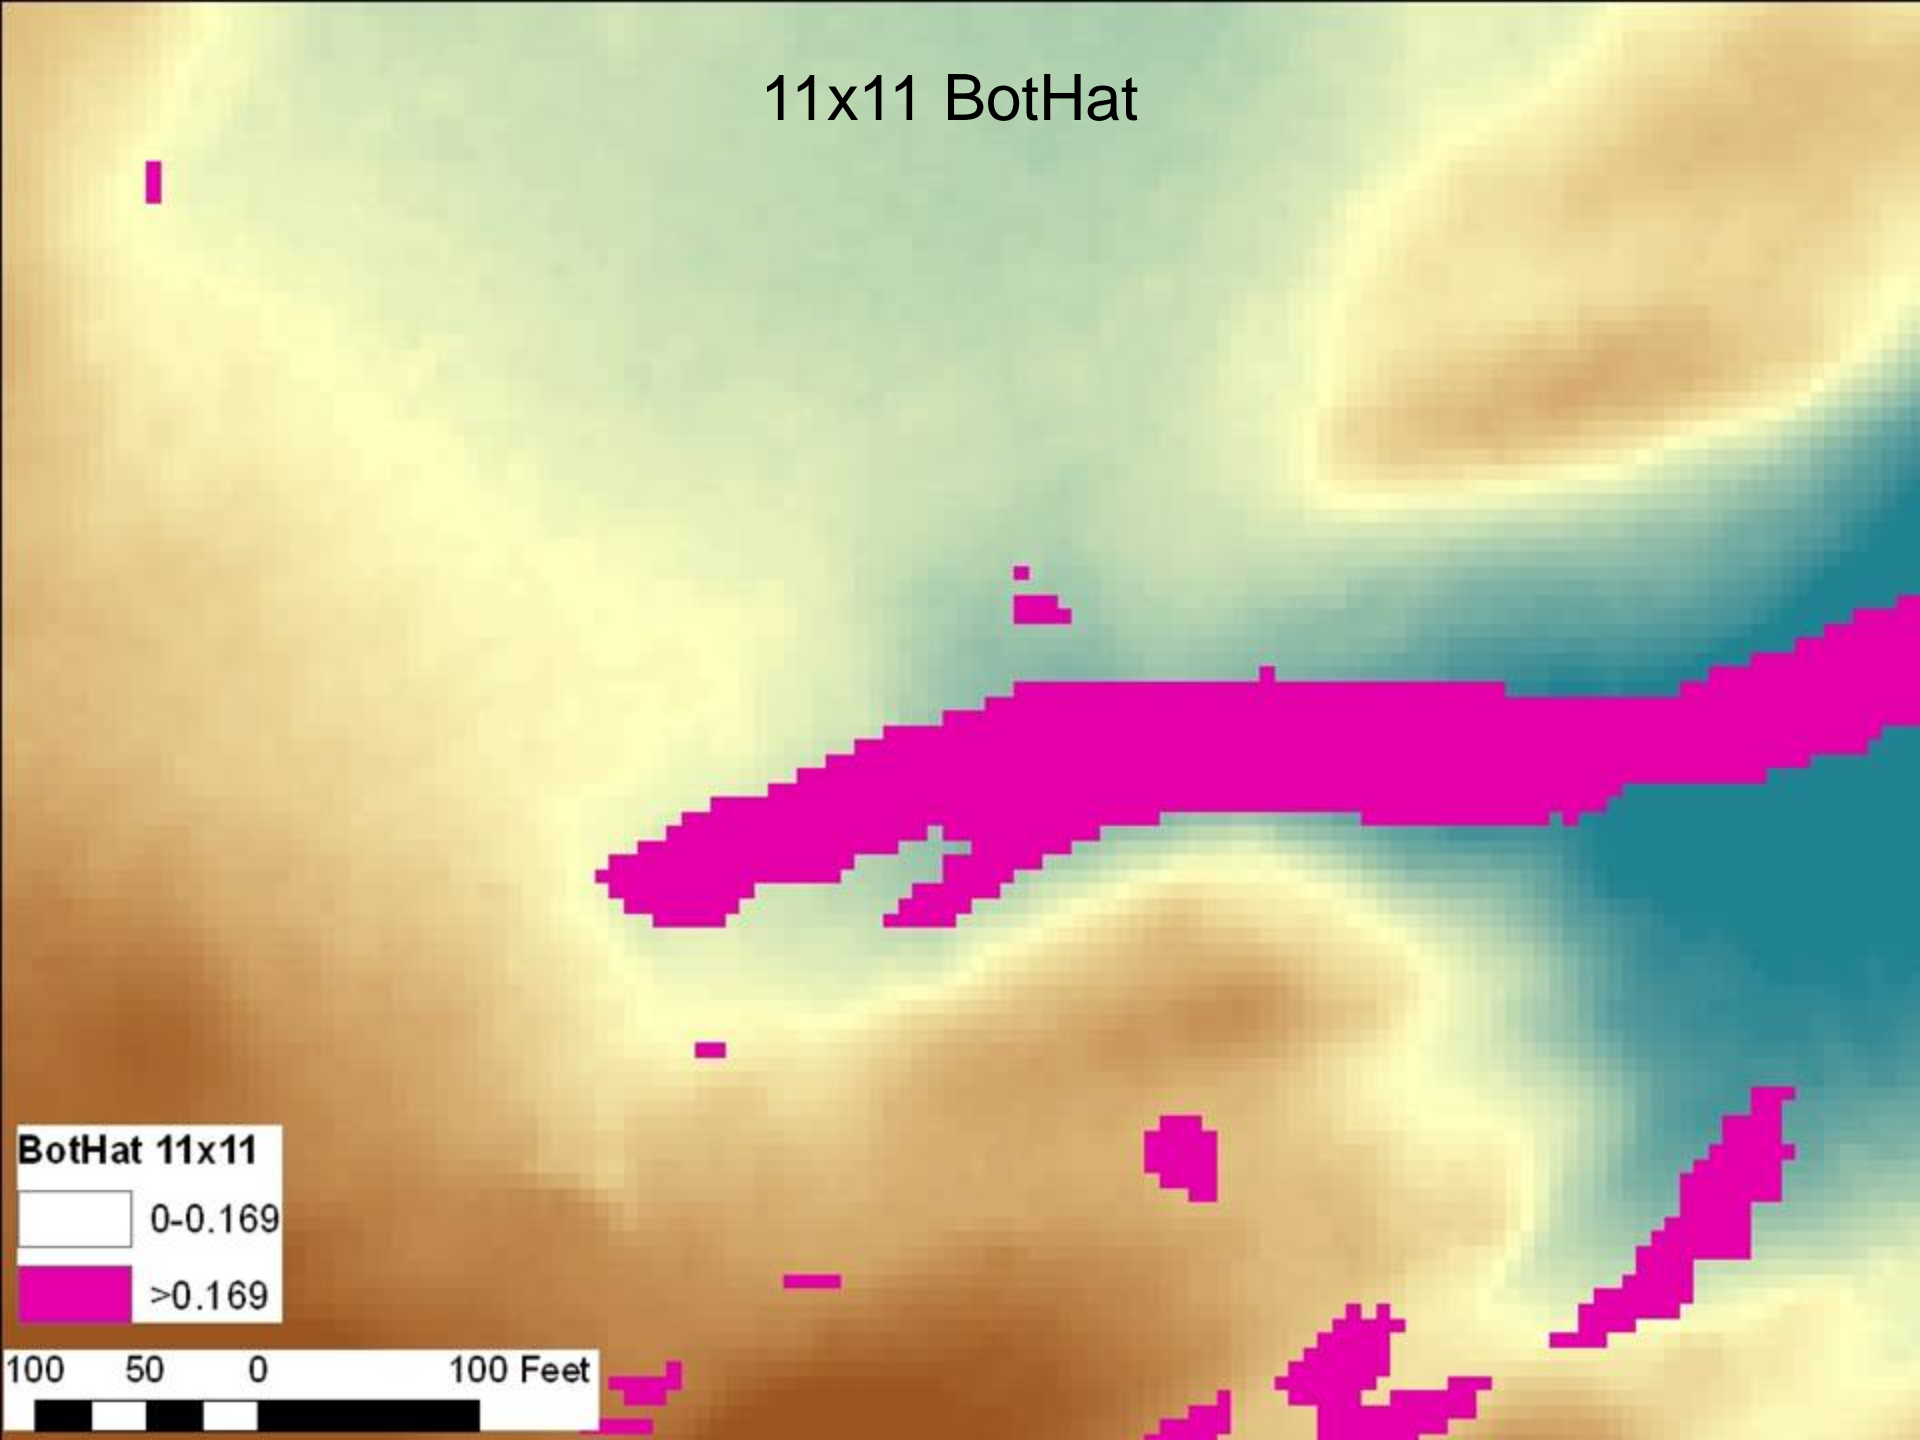

3x3 BotHat

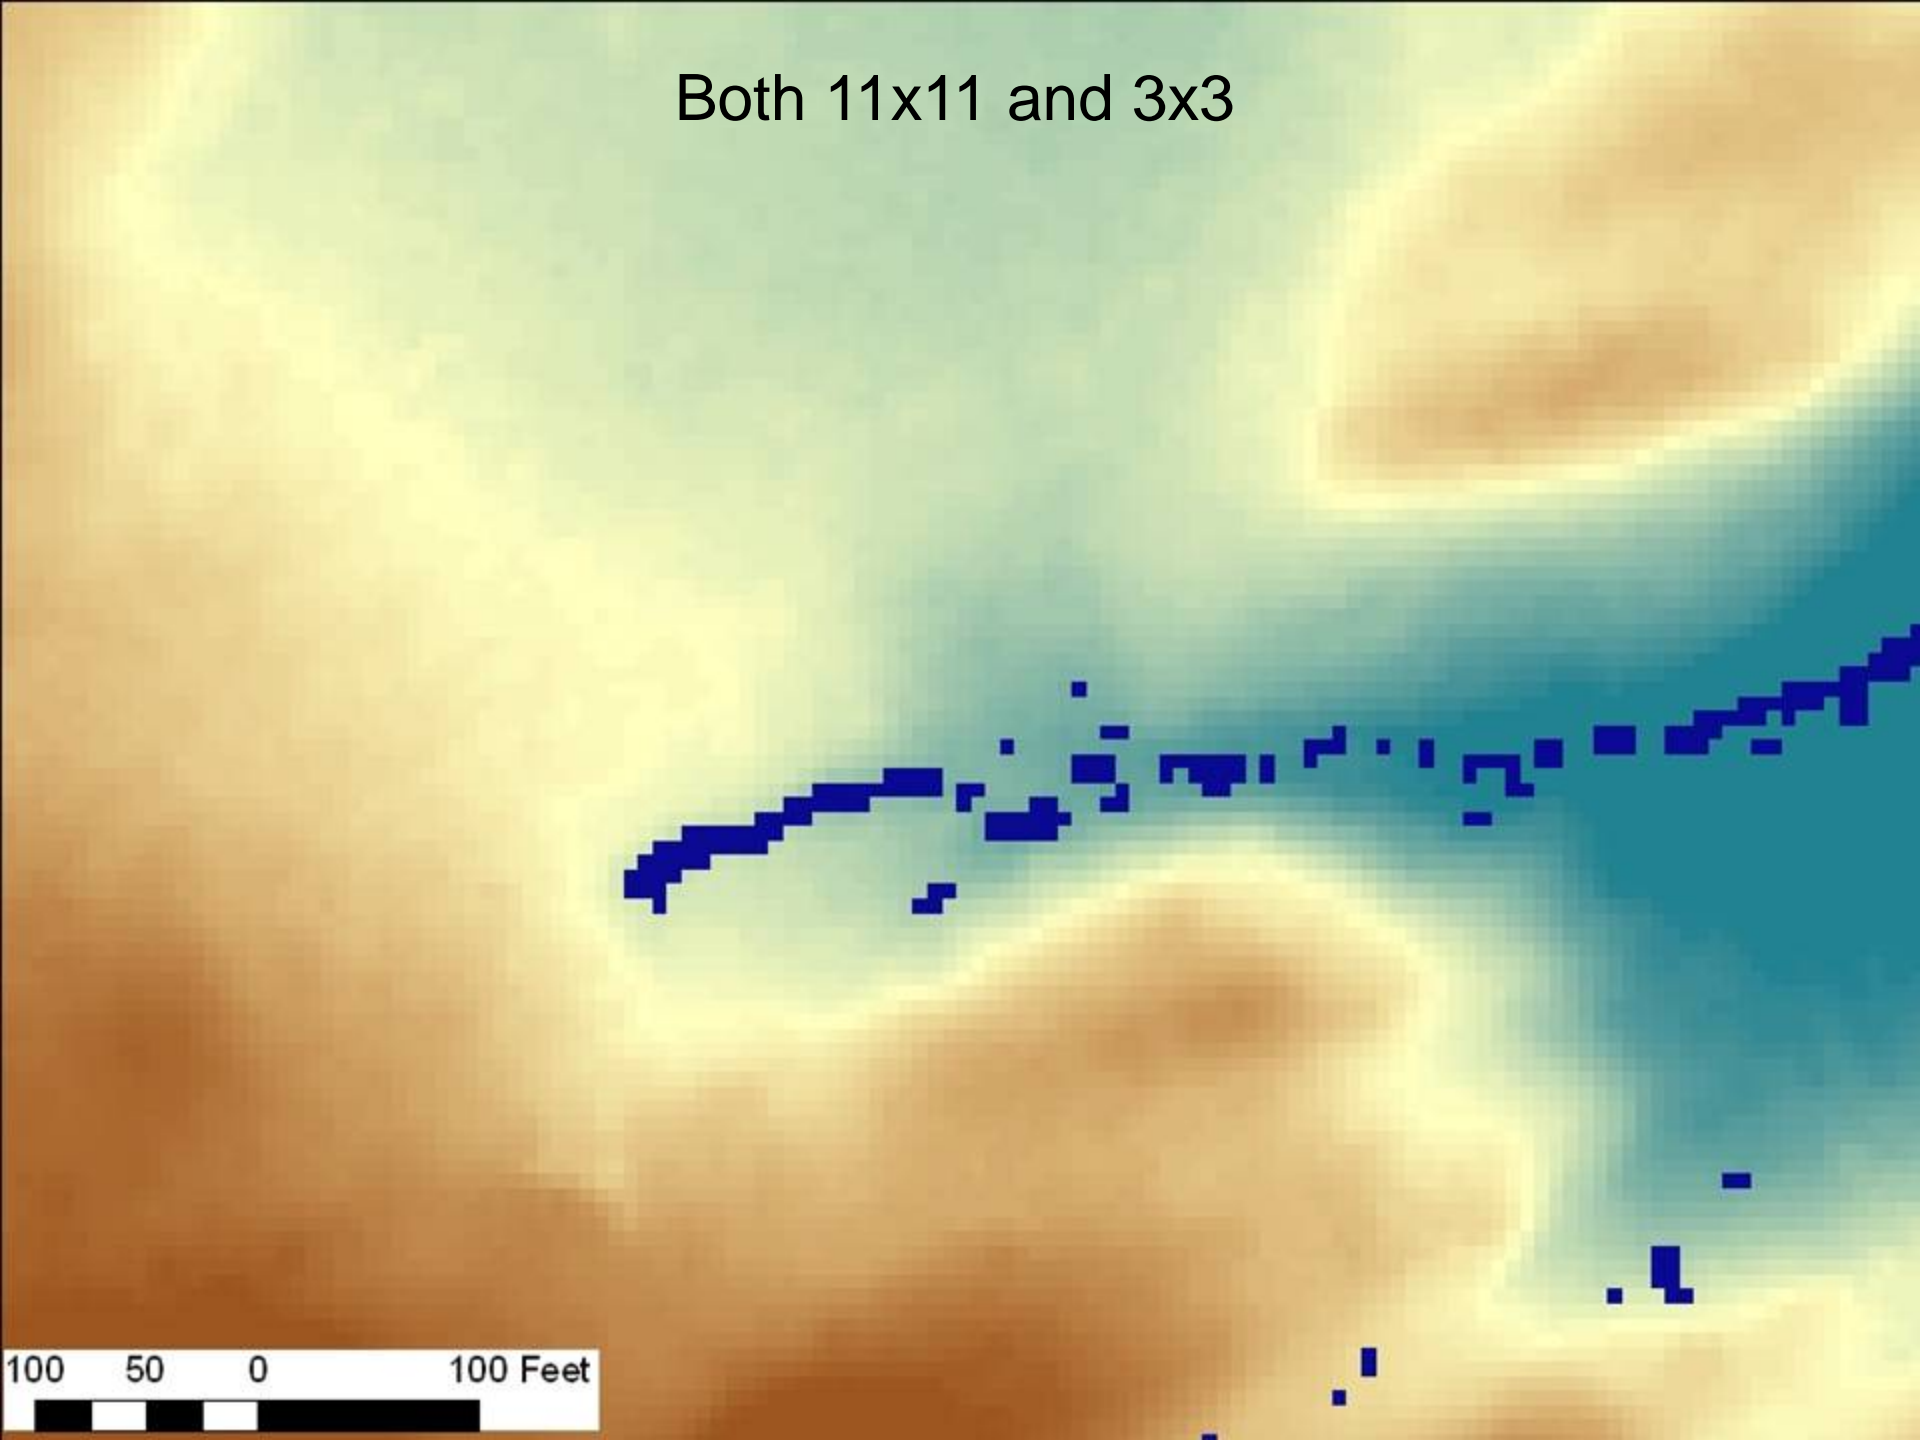

100 50 0 100 Feet

11x11 BotHat

Field Site Scores

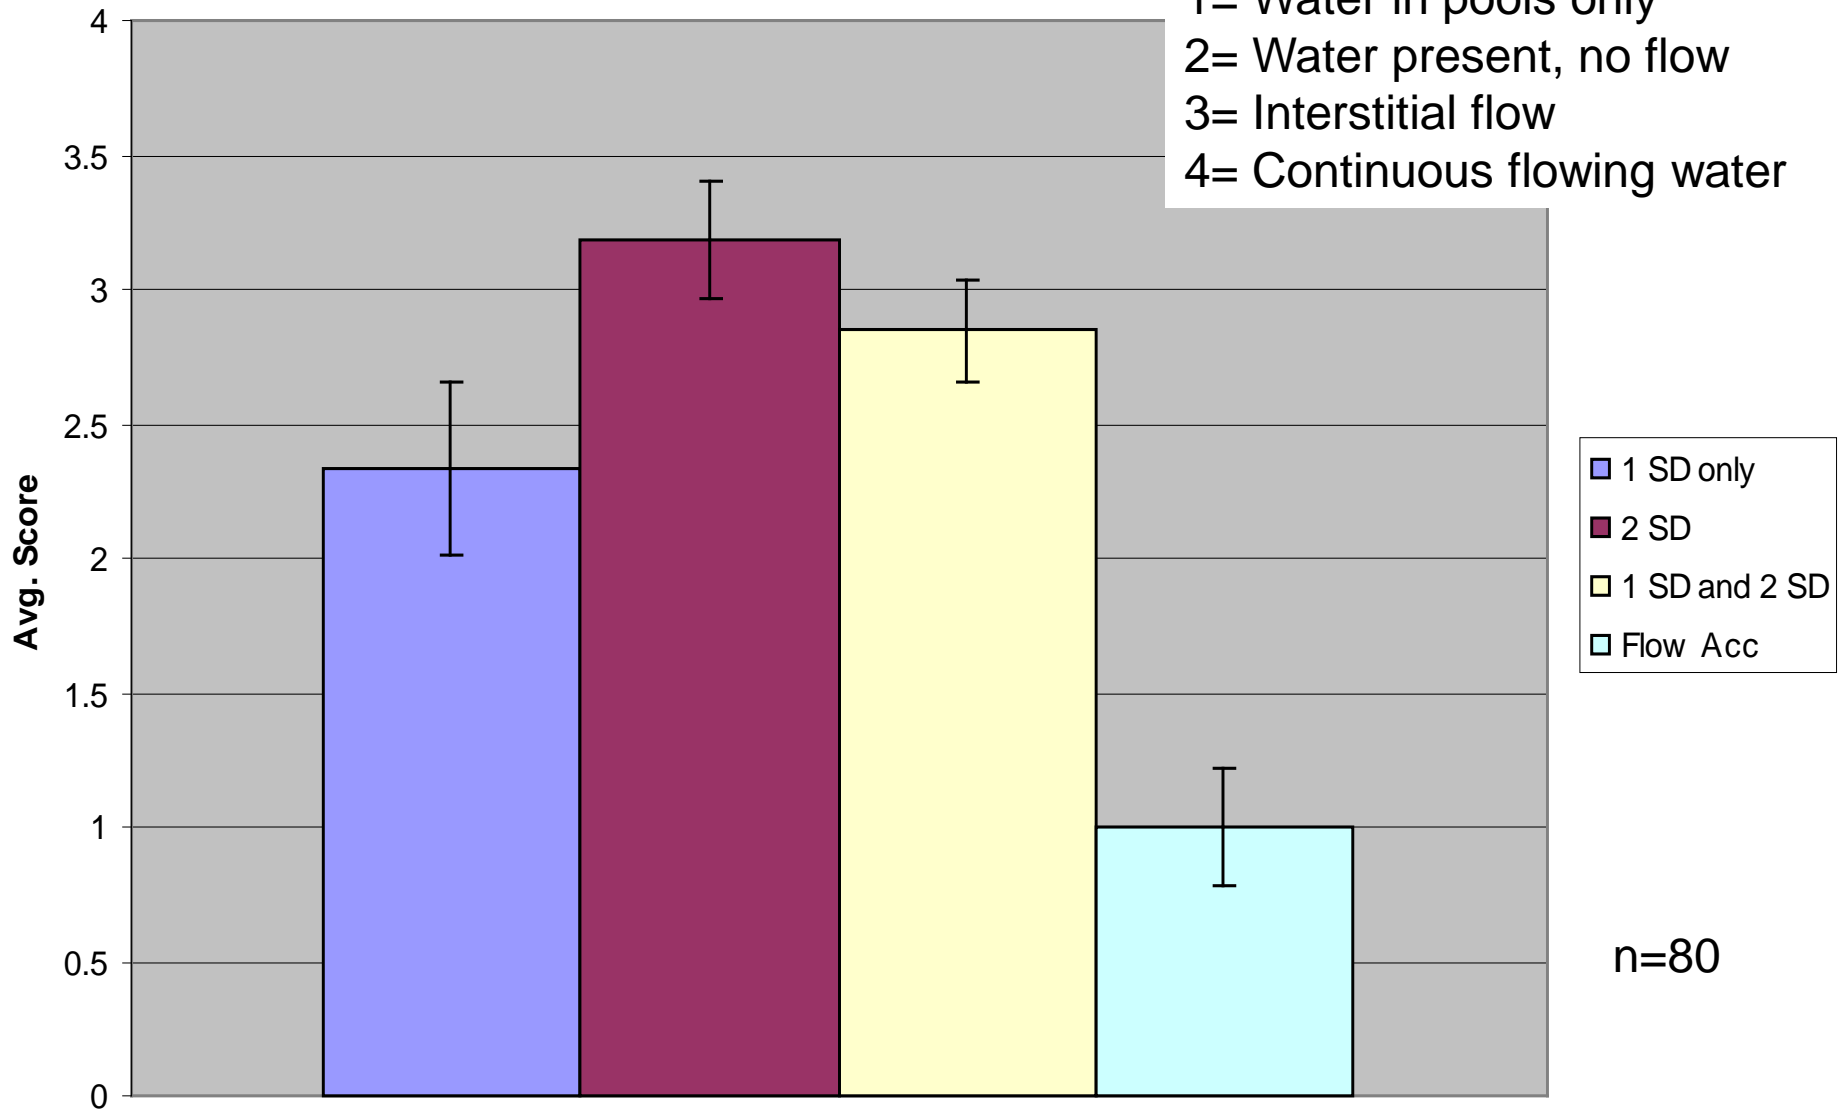

0= No water

1= Water in pools only

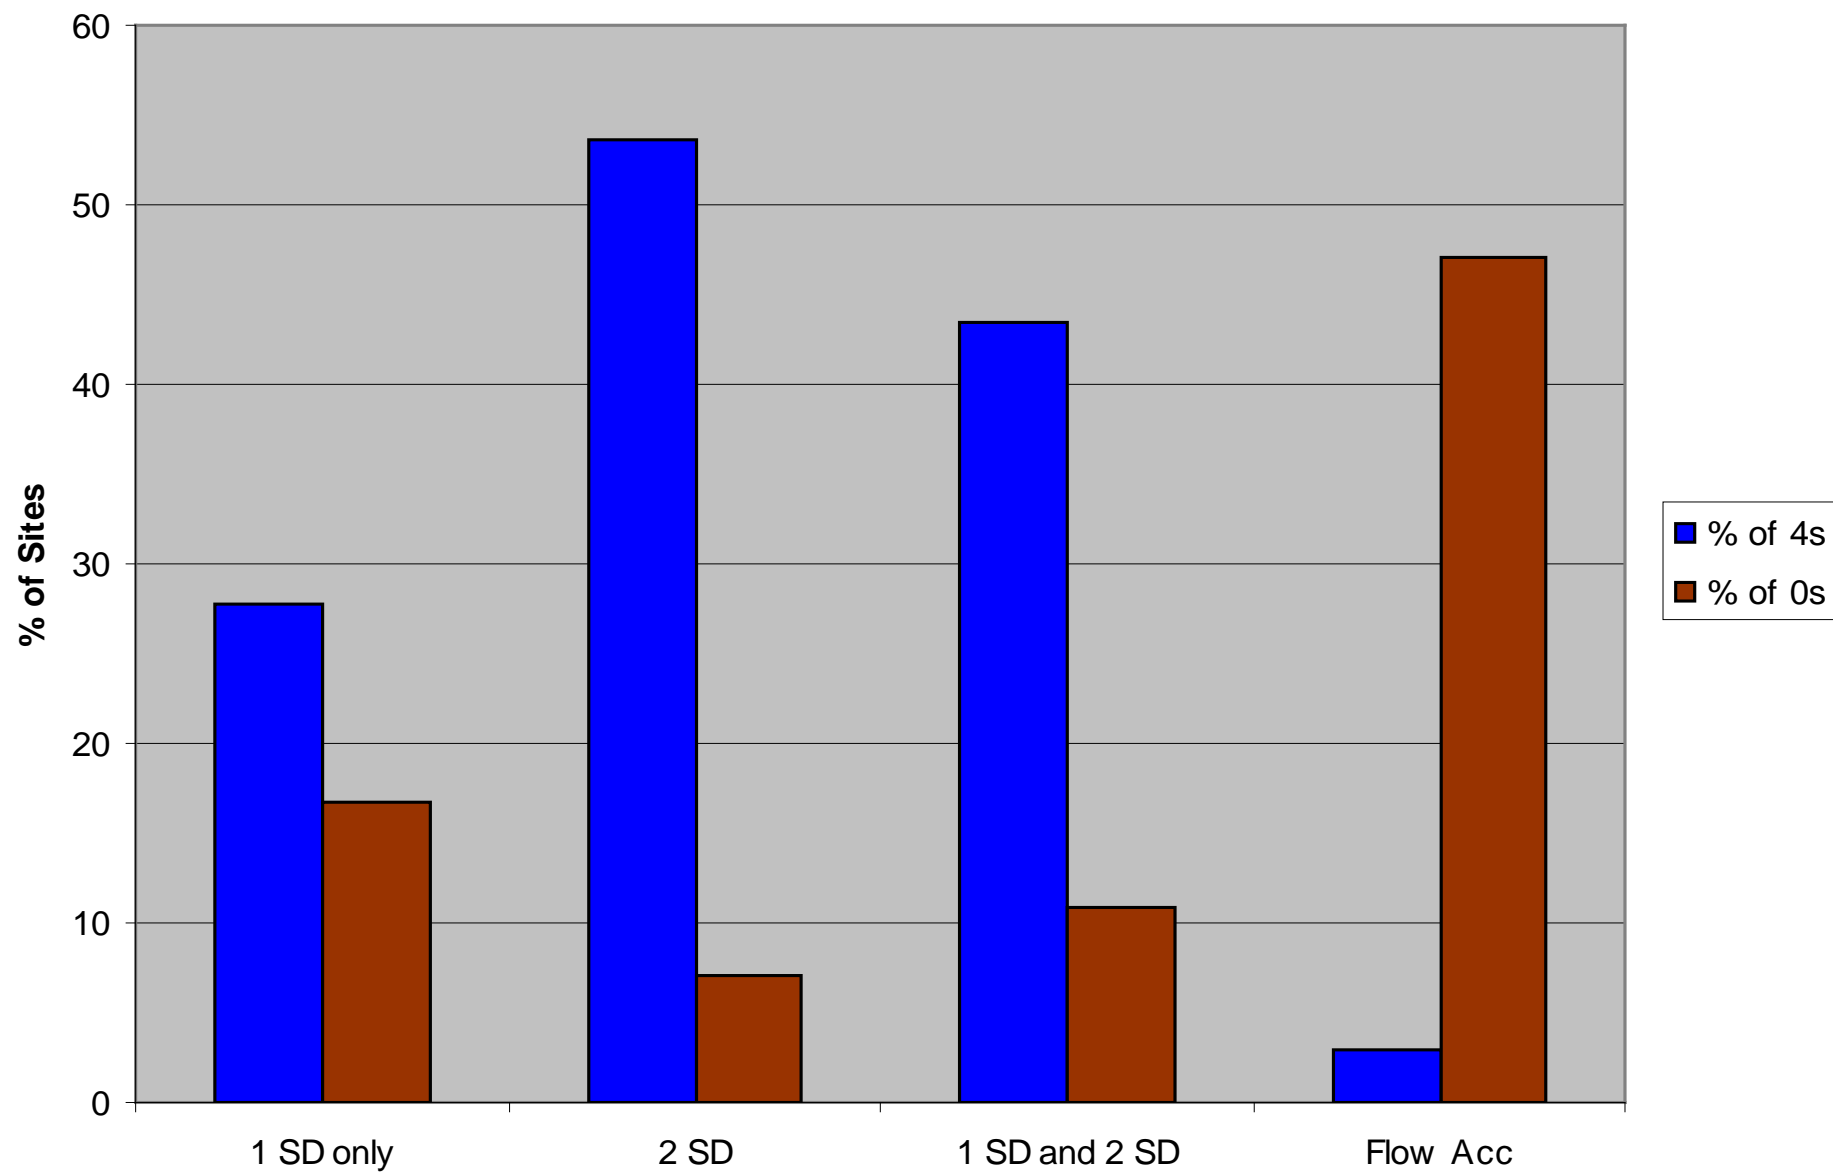

2= Water present, no flow

3= Interstitial flow

4= Continuous flowing water

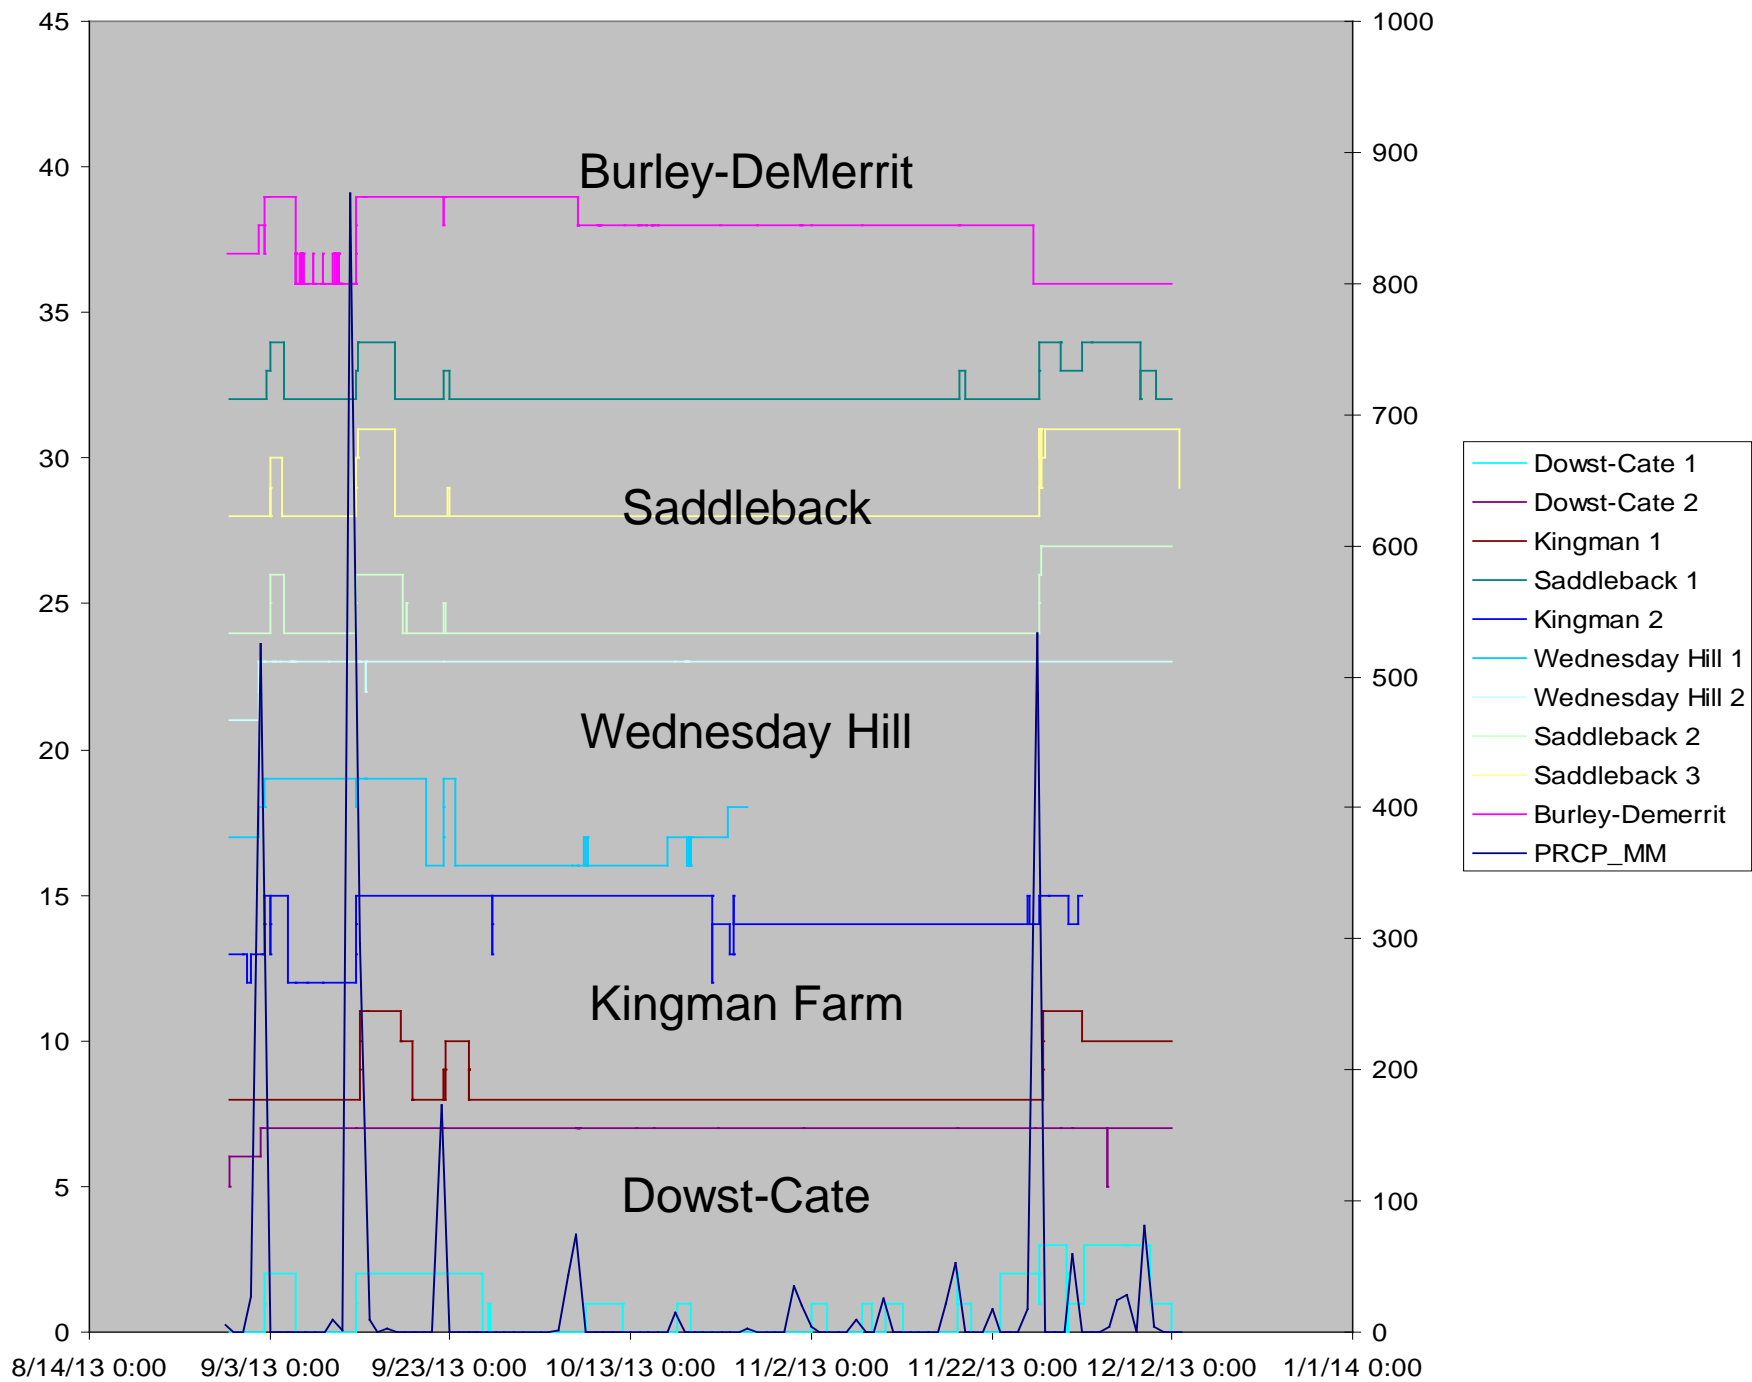

Field Sites

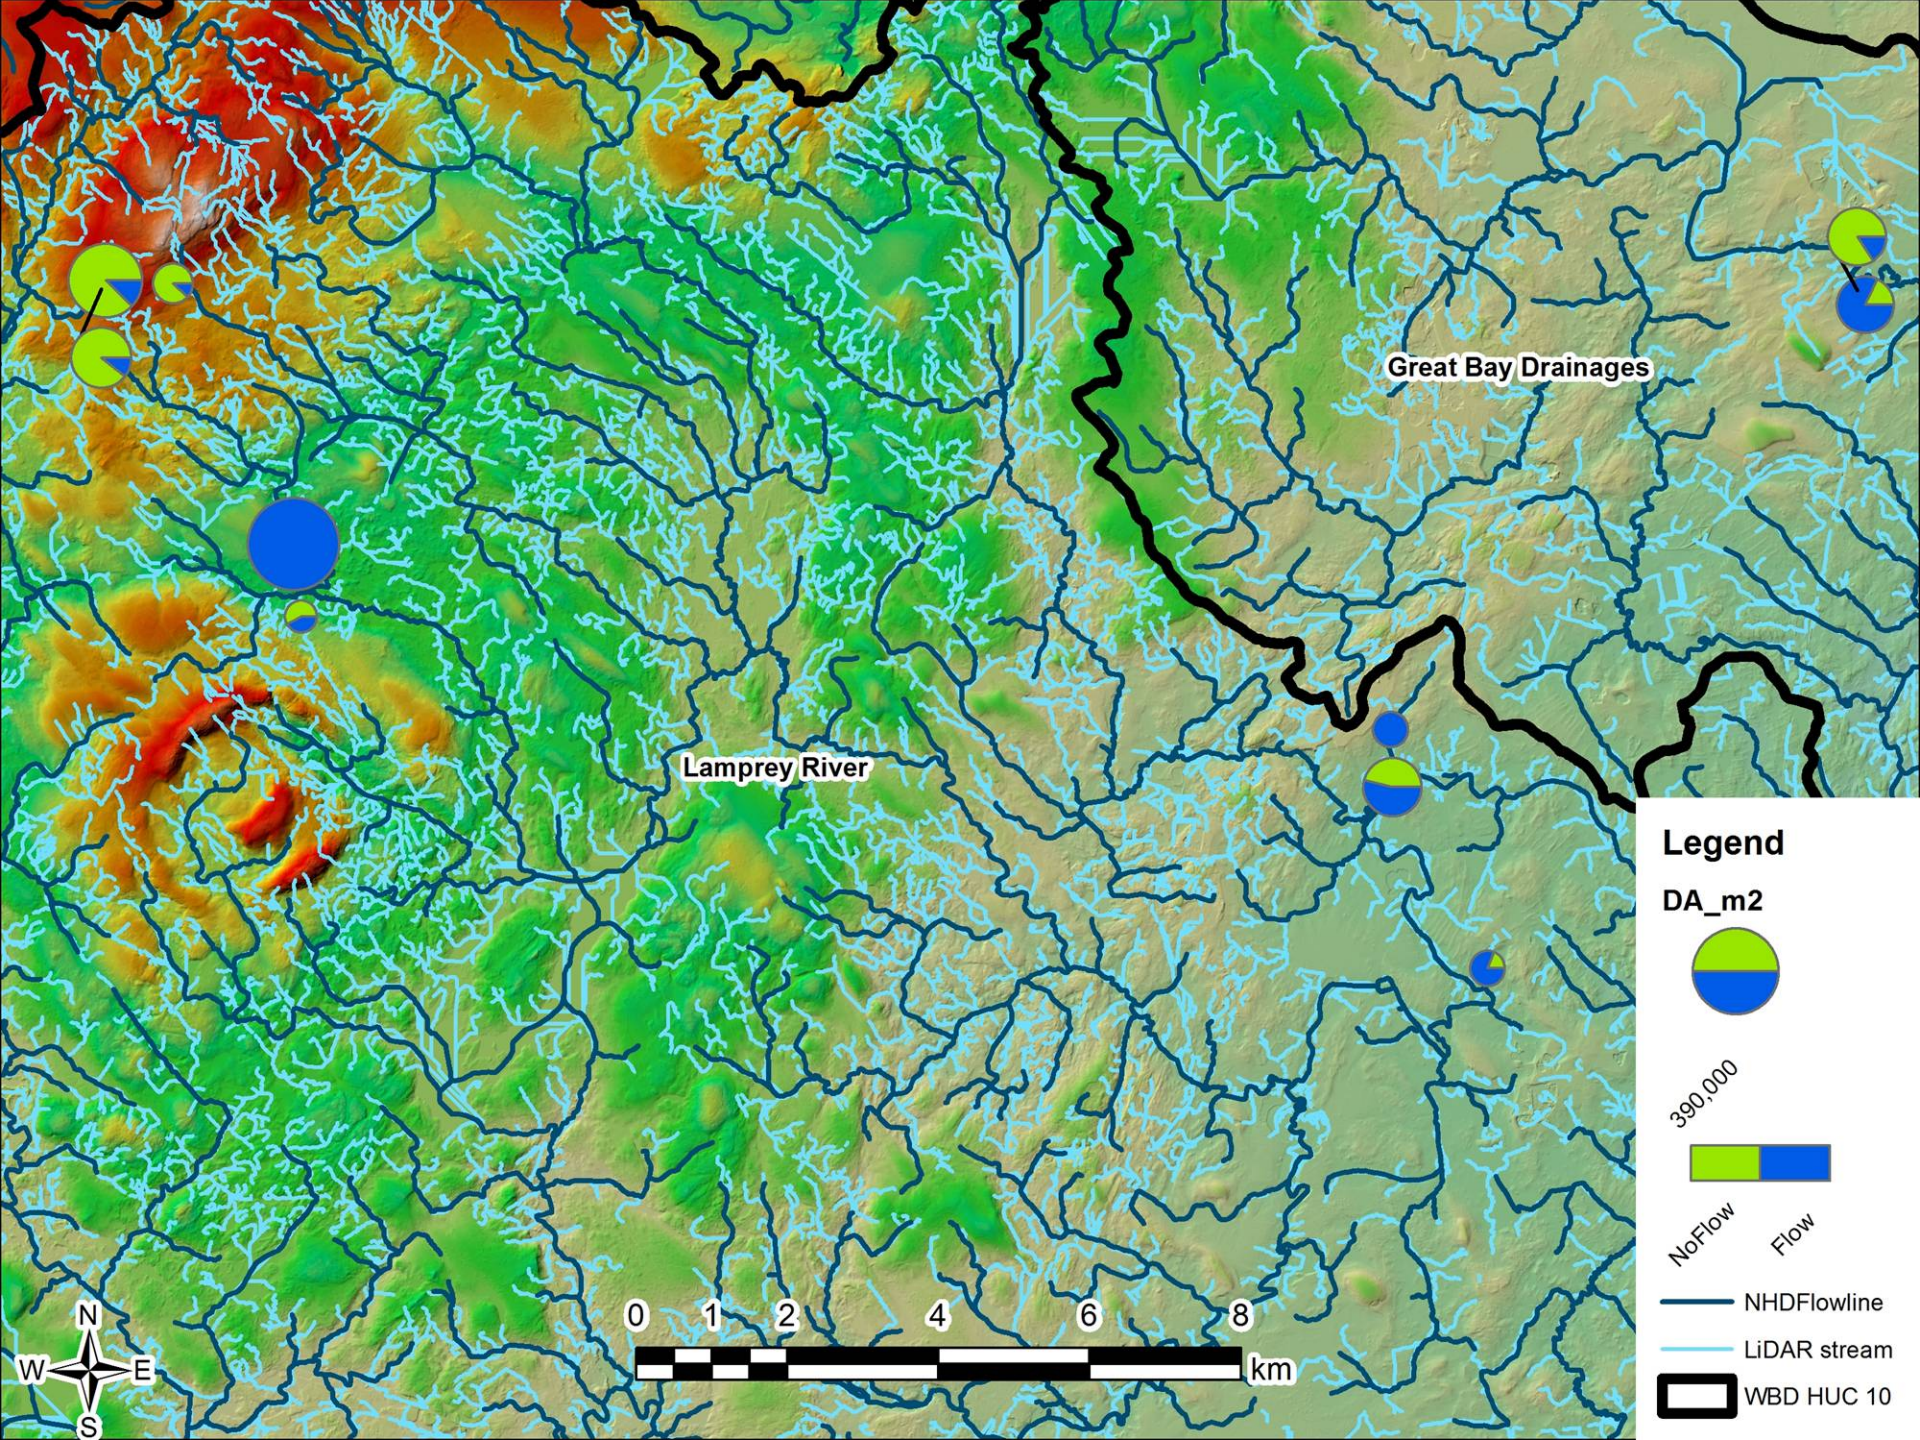

Permanance

- Ten streams in the seacoast region were fitted with simple state sensors following the design of Bhamjee and Lindsay 2011
- Streams were unmapped tributaries to 1st order NHD streams
