

EFFECTS OF LAND USE ON WATER QUALITY IN A CHANGING LANDSCAPE

Principal Investigators: Dr. Jeffrey Schloss, Dr. William McDowell, University of New Hampshire

Descriptors: lake, stream, water quality, nutrients, land use

Problem and Research Objectives:

The waters of New Hampshire represent a valuable water resource contributing to the state's economic base through recreation, tourism, and real estate revenues. Some lakes and rivers serve as current or potential water supplies. For most residents (as indicated by boating and fishing registrations) our waters help to insure a high quality of life. As documented in the 2000 Census, New Hampshire currently leads all of the New England states in the rate of new development and redevelopment. The long-term consequences of the resulting pressure and demands on the state's precious water resources remain unknown. Of particular concern is the response of our waters to increasing non-point source pollutant loadings due to watershed development and land use activities. While in-depth watershed nutrient budget measurements and modeling have been attempted on a small number of watersheds scattered throughout the state, these studies represent only short-term examinations of non-point source pollution nutrient loading. Only a longer-term monitoring program conducted through differing weather years can adequately document the cumulative effects of land use change, quantify the effectiveness of a watershed management program, or assess the accuracy of a specific model of water quality at the landscape scale.

The proposed investigation would allow for the improvement of predictive models used for watershed planning and management. The benefits of this would include 1) assisting watershed stewardship education efforts throughout the state and region; 2) providing existing watershed-based programs like the EPA Basins Model Initiative, the statewide Unified Watershed Assessment Initiative (under the federal Clean Water Action Program) as well as regional initiatives (US EPA Region 1 and NE states) data needed to develop total maximum daily loading criteria (TMDLs) and nutrient criteria for lakes, rivers and streams; and 3) complementing ongoing efforts to predict receiving water response to nutrient loading for source water protection planning. New data generated by this project will be included in our submissions to EPA's new STORET and will be used use in a collaborative, web-based water quality data distribution project between UNH and the NH Department of Environmental Services.
